

A Guide On Proxies (written in comic sans, the best font)

Proxies are a 'low resolution' copy of your video footage that offer several benefits

- 1) Smaller file size (Use up less space on your computer, and is faster to transfer to others)
- 2) Better codec for editing (Your video editor is more efficient and therefore faster to edit)

When you create a proxy copy, whilst editing you do not have to have the original full quality video file present. You only need the original full quality files when you do your final render / export!

For example – if you have the original files on an external storage drive; after you create a proxy, you can safely keep that external storage drive at home and edit outside with the proxy copies!

Editing and distributing proxies is a great way to speed up the video editing process – especially when you need to collaborate with other people (i.e. other editors). Since the size of the proxy file is smaller than the original quality files – the time to upload the video footage will be quicker, meaning that others can download the files faster, meaning others can start editing faster!

You can then let the original quality video files upload (slowly bc Australia), for others to eventually download and render with when they are done editing!

WOW SO COOL HOW TO IS DO?

Depends on your video editor!

I recommend Googling "How to use proxies in (name of your vide editor)"
